Paper Synthesis

Paper: devine-1989-stereotypes-and-prejudice--their-automatic-and-controlled-components

Executive Summary

The paper investigates whether automatic activation of Black-related stereotypes operates similarly for high- and low-prejudice White participants and whether controlled processes can inhibit such activation. Across three experiments, it finds equivalent stereotype knowledge and automatic, stereotype-congruent evaluations in both groups, but only low-prejudice individuals demonstrate controlled inhibition of automatically activated stereotype-congruent thoughts. These results support a dual-process model that separates automatic stereotype activation from the controlled inhibition required for nonprejudiced responses.

Reading Recommendation

Read Selectively

The paper offers a noteworthy dual-process model and converging evidence across three experiments, but methodological gaps (e.g., undocumented sample sizes) and moderate concerns about task validity and overgeneralization limit its impact. Senior readers should skim the abstract and general discussion for the theoretical claim, then focus on the methods and results of Study 3 (thought-listing) to assess the evidence for controlled inhibition.

Background and Motivation

The paper addresses the unresolved gap concerning whether high- and low-prejudice individuals differ or are similar in their automatic and controlled responses to stereotyped group members, specifically the assumption that both groups possess equivalent cultural stereotype knowledge yet diverge in controlled inhibition. This gap is motivated by classic findings that stereotypes form early (Allport 1954) and are automatically activated (Higgins & King 1981) as well as evidence that well-learned associations can operate independently of personal endorsement (Dovidio, Evans & Tyler 1986).

Theoretical Stance

Overall stance: Consistent Theoretical

The introduction articulates the dual-process model as the central hypothesis, and the general discussion repeatedly interprets all three studies as supporting that model, without abandoning or contradicting it.

Theories Discussed

- **Automatic-controlled processes model of prejudice (*focal*):** A dual-process framework positing that cultural stereotype knowledge is automatically activated for all individuals, while nonprejudiced responses require controlled inhibition of the automatic stereotype and activation of personal beliefs.
- **Inevitability of prejudice framework (*alternative*):** Claims that as long as cultural stereotypes exist, prejudice inevitably follows because stereotypes are automatically applied to group members, minimizing the role of controlled processes.
- **Tripartite model of attitudes (*alternative*):** Treats stereotypes as the cognitive component of attitudes, without separating automatic activation from controlled belief processes.
- **Posner & Snyder information-processing model (1975) (*background*):** General model of automatic vs controlled information processing cited to ground the dual-process approach.
- **Schneider & Shiffrin automatic-controlled processes (1977) (*background*):** Theoretical work on the independence of automatic and controlled processes, used as a conceptual foundation.
- **Dovidio, Evans & Tyler (1986) - well-learned associations (*background*):** Empirical support that stereotypes function as entrenched associative networks that can be automatically activated.

- **Higgins & King (1981) - gender stereotype activation** (*background*): Evidence that stereotypes can be automatically activated even when the target category is not salient.
- **Allport (1954) - early formation of stereotypes** (*background*): Classic work establishing that stereotypes are acquired early in development.

Study Design

- **Number of experiments:** 3
- **Predictors examined:** prejudice level (high vs low)
- **Outcomes examined:** knowledge of cultural Black stereotype (free-response content), evaluation of ambiguous stereotype-relevant behaviors (congruent vs incongruent ratings), thought-listing of stereotype-congruent vs equality-focused thoughts (inhibition index)
- **Materials:** All experiments used stimuli related to Black-White intergroup contexts: (1) a free-response task eliciting participants' stereotypic attributes for Blacks; (2) brief descriptions of ambiguous behaviors that could be interpreted as stereotypically positive or negative, presented after a priming manipulation; (3) a directed thought-listing task in which participants generated thoughts about a target person after exposure to a stereotyped cue.
- **Design types:**
 - exp_1: between-subjects comparison of high- vs low-prejudice participants on a free-response stereotype knowledge task
 - exp_2: within-subjects evaluation of ambiguous behaviors following a pre-exposure that precludes conscious monitoring, with prejudice level as a between-subjects factor
 - exp_3: mixed design; between-subjects prejudice level with a within-subjects thought-listing task assessing controlled inhibition of automatically activated stereotype-congruent thoughts

Findings Summary

Across the three studies, high- and low-prejudice participants showed equivalent knowledge of the Black cultural stereotype (Study 1) and produced similarly stereotype-congruent evaluations of ambiguous behaviors when conscious monitoring was blocked (Study 2), indicating that automatic activation operates independently of prejudice level. In contrast, only low-prejudice participants demonstrated controlled inhibition of automatically activated stereotype-congruent thoughts, replacing them with equality-focused thoughts in the directed thought-listing task (Study 3). Thus, while automatic stereotype activation appears uniform across prejudice groups, the capacity for controlled inhibition differentiates low- from high-prejudice individuals.

Evidence-Claim Alignment

Supported Claims

- High- and low-prejudice participants possess equivalent knowledge of the cultural Black stereotype (Study 1 finding supports the claim of equal stereotype knowledge).
- Automatic stereotype activation influences evaluations of ambiguous behaviors for both high- and low-prejudice participants when conscious monitoring is precluded (Study 2 finding supports the claim that automatic activation operates independently of prejudice level).
- Low-prejudice participants can inhibit automatically activated stereotype-congruent thoughts and replace them with equality-focused thoughts in a directed thought-listing task (Study 3 finding supports the claim that controlled processes enable inhibition of automatic prejudice for low-prejudice individuals).

Unsupported or Weakly Supported Claims

- The assertion that automatic stereotype activation is equally strong and inescapable for high- and low-prejudice participants (Study 2 measures downstream evaluations, not direct activation strength, weakening support for the claim of equal activation magnitude).
- The general claim that controlled processes can inhibit automatic prejudice for all individuals (Study 3 shows inhibition only among low-prejudice participants, leaving the claim about high-prejudice participants unsupported).
- The broad statement that automatically activated stereotype-congruent responses are independent of one's current attitudes or beliefs (Evidence is limited to Black-White stimuli with White participants, so the claim lacks generalizability beyond this context).

Contradictions or Tensions

- Study 3 demonstrates inhibition of automatic stereotypes only in low-prejudice participants, yet the general discussion extrapolates this to a universal mechanism applicable to all participants, creating a tension between the empirical result and the theoretical generalization.
- The free-response stereotype knowledge task in Study 1 may conflate cultural knowledge with personal belief or socially desirable responding, challenging the claim of equal stereotype knowledge across prejudice levels.
- The thought-listing task in Study 3 could be influenced by demand characteristics or self-presentation motives, raising tension between the observed inhibition effects and the claim that they reflect pure controlled cognitive inhibition.

Strengths

- Clear dual-process theoretical framework that distinguishes automatic stereotype activation from controlled inhibition, grounding the model in classic information-processing literature (Posner & Snyder, 1975; Schneider & Shiffrin, 1977).
- Consistent empirical pattern across three experiments: Study 1 shows equivalent stereotype knowledge for high- and low-prejudice participants; Study 2 demonstrates stereotype-congruent evaluations of ambiguous behavior when conscious monitoring is blocked; Study 3 provides evidence that low-prejudice participants can inhibit automatically activated stereotype-congruent thoughts.
- Use of distinct methodological approaches to tap automatic (free-response knowledge, ambiguous-behavior evaluation) and controlled (thought-listing) processes, offering converging evidence for the model's core predictions.
- Transparent articulation of mechanistic claims (e.g., frequency of activation increases accessibility; controlled inhibition requires cognitive capacity), linking observed effects to well-established cognitive theories (Neely, 1977).
- Thoughtful discussion of alternative accounts, particularly the inevitability-of-prejudice framework, and explicit argument that the data support a non-inevitable view of prejudice.
- Integration of findings across studies in the general discussion, summarizing how automatic activation appears independent of prejudice level while controlled inhibition differentiates low- from high-prejudice individuals.

Weaknesses and Concerns

- Study 1's free-response stereotype-knowledge task may conflate cultural knowledge with personal belief or socially desirable responding, threatening the test of the hypothesis that high- and low-prejudice individuals possess equivalent stereotype knowledge.
- Study 2 infers equal strength of automatic activation from downstream ambiguous-behavior evaluations, but the task does not directly measure activation magnitude (e.g., priming latency), leaving the claim of equivalent automatic activation over-stated.
- Study 3's thought-listing paradigm can be influenced by demand characteristics and self-presentation motives, making it unclear whether observed non-stereotypic thoughts reflect genuine controlled inhibition or strategic impression management.
- The authors generalize that controlled processes can inhibit automatic prejudice for all participants, yet empirical evidence shows inhibition only among low-prejudice subjects,

resulting in an overreach beyond the data.

- Methodological reporting is incomplete: sample sizes, power analyses, and exclusion criteria are absent for all three experiments, limiting assessment of statistical power and generalizability.
- The tripartite model of attitudes is introduced as an alternative theory but is never empirically addressed or contrasted with the focal model, leaving the comparative theoretical contribution underdeveloped.

Abstract

Preserved from source without summarization.

Three studies tested basic assumptions derived from a theoretical model based on the dissociation of automatic and controlled processes involved in prejudice. Study 1 supported the model's assumption that high- and low-prejudice persons are equally knowledgeable of the cultural stereotype. The model suggests that the stereotype is automatically activated in the presence of a member (or some symbolic equivalent) of the stereotyped group and that low-prejudice responses require controlled inhibition of the automatically activated stereotype.

Study 2, which examined the effects of automatic stereotype activation on the evaluation of ambiguous stereotype-relevant behaviors performed by a race-unspecified person, suggested that when subjects' ability to consciously monitor stereotype activation is precluded, both high- and low-prejudice subjects produce stereotype-congruent evaluations of ambiguous behaviors. Study 3 examined high- and low-prejudice subjects' responses in a consciously directed thought-listing task. Consistent with the model, only low-prejudice subjects inhibited the automatically activated stereotype-congruent thoughts and replaced them with thoughts reflecting equality and negations of the stereotype. The relation between stereotypes and prejudice and implications for prejudice reduction are discussed.

Introduction (Paper-Level)

Section: paper-level

Research Gap / Motivation

It remains unclear how high- and low-prejudice individuals differ or are similar in their automatic and controlled responses to target group members.

Theoretical Framework

automatic vs controlled processes

The present model ... suggests that automatic and controlled processes involved in stereotypes and prejudice can be dissociated, positing that the inevitability of prejudice arguments follow from tasks that are likely to engage automatic processes on which those high and low in prejudice are presumed not to differ.

- Citations: Posner & Snyder (1975); Schneider & Shiffrin (1977)

stereotype activation as automatic

The model holds that this unintentional activation of the stereotype is equally strong and equally inescapable for high- and low-prejudice persons.

- Citations: Dovidio, Evans, & Tyler (1986)

personal beliefs require controlled processing

Activation of personal beliefs require conscious attention. Nonprejudiced responses require both the inhibition of the automatically activated stereotype and the intentional activation of nonprejudiced beliefs.

- Citations: Higgins & King (1981)

Specific Hypotheses / Predictions

equal stereotype knowledge across prejudice levels

The present model assumes that ... high- and low-prejudice persons are equally knowledgeable of the cultural stereotype of Blacks.

- Citations: Brigham (1972); Ehrlich (1973)

low-prejudice requires controlled inhibition

Because the stereotype has a longer history of activation ... overt nonprejudiced responses require intentional inhibition of the automatically activated stereotype and activation of the newer personal belief structure.

automatic activation influences subsequent processing even without endorsement

If a stereotype is automatically activated ... those who reject the cultural stereotype do not (or perhaps cannot) monitor consciously this activation, information activated in the stereotype could influence subsequent information processing.

Mechanistic Claims

frequency of activation increases accessibility

Stereotypes have a longer history of activation and are therefore likely to be more accessible than are personal beliefs.

conflict between stereotype and personal belief

To the extent that an individual rejects the stereotype, he or she experiences a fundamental conflict between the already established stereotype and the more recently established personal beliefs.

controlled inhibition requires cognitive capacity

Before such inhibition of automatically activated responses can occur, there has to be enough time and cognitive capacity available for the conscious expectancy to develop and inhibit the automatic processes.

- Citations: Neely (1977)

Constructs of Interest

- **prejudice level (high vs low)** (*predictor*): Individual differences in endorsement of negative stereotypes about Blacks.

- **responses to stereotyped group members** (*outcome*): Behavioral or evaluative judgments that may reflect automatic stereotype activation or controlled inhibition.

Rationale for Predictor

Prejudice level is expected to determine whether personal beliefs overlap with cultural stereotypes, influencing the need for controlled inhibition.

Rationale for Outcome

Responses reveal the operation of automatic versus controlled processes in prejudice, allowing assessment of the model's predictions.

Key Terminology

automatic processes: Unintentional or spontaneous activation of well-learned associations that occur without conscious effort.

Automatic processes involve the unintentional or spontaneous activation of some well-learned set of associations or responses that have been developed through repeated activation in memory.

controlled processes: Intentional, effortful mental operations that require active attention and can inhibit automatic responses.

Controlled processes are intentional and require the active attention of the individual.

personal beliefs: Newer cognitive structures representing endorsed propositions about a group, distinct from cultural stereotypes.

Personal beliefs (i.e., decisions about the appropriateness of stereotypic ascriptions) are necessarily newer cognitive structures.

Background Research

- Allport (1954) showed that stereotypes are established early in children's memories.
- Higgins & King (1981) demonstrated that gender stereotypes are automatically activated when gender is not salient.
- Neely (1977) found that automatic semantic priming can be overridden by conscious expectancies given sufficient time.

Alternative Theories Discussed

inevitability of prejudice framework

- **Description:** Posits that as long as cultural stereotypes exist, prejudice inevitably follows because stereotypes are automatically applied to group members.
- **Difference from focal theory:** It equates knowledge of a stereotype with prejudice, ignoring the distinction between stereotype knowledge and personal belief endorsement.
- **Citations:** Allport (1954); Ehrlich (1973)

tripartite model of attitudes

- **Description:** Treats stereotypes as the cognitive component of prejudiced attitudes.
- **Difference from focal theory:** Focuses on attitudes rather than separating automatic stereotype activation from controlled belief processes.
- **Citations:** Harding, Proshansky, Kutner, & Chein (1969)

Overview of Studies

Study 1 tests equal stereotype knowledge across prejudice levels; Study 2 examines automatic stereotype priming on ambiguous behavior evaluation; Study 3 assesses controlled inhibition via a thought-listing task.

Missing or Unclear

- Explicitly numbered hypotheses are not provided; predictions are embedded in narrative.
- Quantitative definitions of 'high' vs 'low' prejudice are not detailed in the introduction.

Additional Quoted Evidence

The present model assumes that ... high- and low-prejudice persons are equally knowledgeable of the cultural stereotype of Blacks.

Activation of personal beliefs require conscious attention. Nonprejudiced responses require both the inhibition of the automatically activated stereotype and the intentional activation of nonprejudiced beliefs.

If a stereotype is automatically activated ... information activated in the stereotype could influence subsequent information processing.

Experiment 1 -- Introduction

Section: exp_1

Rationale for This Experiment

The experiment was conducted to validate the present model by directly examining whether high- and low-prejudice individuals differ in their knowledge of the cultural stereotype of Blacks, addressing a gap in the literature.

Relation to Prior Experiments

This is the first experiment in the series; it establishes baseline knowledge differences before later experiments manipulate other variables.

Specific Predictions

knowledge equivalence across prejudice levels

The assumption that high- and low-prejudice subjects are equally knowledgeable of the cultural stereotype has not been documented.

- Citations: Brigham (1971)

New Elements Introduced

- Use of a free-response task instead of the typical adjective checklist to assess stereotype content
- Direct comparison of high-prejudice versus low-prejudice participants' knowledge

Constraints Addressed

- Addresses the limitation of previous checklist assessments that may cue participants and obscure true knowledge differences
- Tests the assumption of equal stereotype knowledge across prejudice levels

Missing or Unclear

- Explicit statement of the directional hypothesis (e.g., whether high-prejudice participants will know more or less)
- Details on how knowledge will be quantified or scored

Citations Referenced

General Discussion

Section: paper-level

Summary of Findings

Studies 1 and 2 show that both high- and low-prejudice individuals possess knowledge of racial stereotypes and exhibit equally strong automatic stereotype activation. Study 3 demonstrates that controlled processes can inhibit these automatic effects when goals to maintain a nonprejudiced identity are salient, suggesting that prejudice is not inevitable but depends on the capacity for controlled inhibition.

Theoretical Conclusions

controlled processes inhibit automatic prejudice

Study 3, however, provided evidence that controlled processes can inhibit the effects of automatic processing when the implications of such processing compete with goals to establish or maintain a nonprejudiced identity.

automatic activation independent of attitudes

It would appear that the automatically activated stereotype-congruent or prejudice-like responses have become independent of one's current attitudes or beliefs.

habit-breaking analogy for prejudice reduction

Inhibiting stereotype-congruent or prejudice-like responses and intentionally replacing them with nonprejudiced responses can be likened to the breaking of a bad habit.

Cross-Experiment Integration

integration of studies 1-3

Study 1 suggested both high- and low-prejudice persons possess knowledge of the racial stereotype... Study 2 suggested that automatic stereotype activation is equally strong and equally inescapable for high- and low-prejudice subjects... Study 3, however, provided evidence that controlled processes can inhibit the effects of automatic processing...

Results Authors State Support Their Theory

automatic stereotype activation equivalence

Study 2 suggested that automatic stereotype activation is equally strong and equally inescapable for high- and low-prejudice subjects.

controlled inhibition evidence

Study 3, however, provided evidence that controlled processes can inhibit the effects of automatic processing when the implications of such processing compete with goals to establish or maintain a nonprejudiced identity.

Results Authors State Challenge a Theory

challenge to inevitability of prejudice

I disagree fundamentally with this premise. Such an argument denies the possibility for change in one's attitudes and beliefs, and I view this as a severe limitation of the Crosby et al. (1980) analysis.

- Citations: Crosby, Bromley, and Saxe (1980)

Alternative Accounts Addressed by Authors

Crosby et al. inevitability of prejudice (*named theory*)

- **Description:** All White Americans are prejudiced and nonprejudiced responses are merely impression-management attempts.
- **How authors addressed it:** argued against; claim it denies possibility of attitude change
- **Citations:** Crosby, Bromley, and Saxe (1980)

Implications for the Field

potential for nonprejudiced behavior

The present framework highlights the potential for nonprejudiced behaviors when social desirability concerns are minimal (Study 3).

need for precise prejudice labeling criteria

What this analysis requires is that theoreticians be more precise on the criteria established for labeling behavior as prejudiced or nonprejudiced.

Limitations Stated by Authors

- The present model and set of empirical studies certainly does not resolve the issue of precise criteria for labeling behavior as prejudiced or nonprejudiced.
- The analysis acknowledges that changing attitudes and beliefs is not likely to be easy or speedy.

Future Directions Proposed by Authors

- Develop a fully articulated model of controlled processes that delineates the cognitive mechanisms involved in inhibition.
- Systematically explore the variables that are likely to engage controlled stereotype-inhibiting processes in intergroup settings.

Critique

Paper: devine-1989-stereotypes-and-prejudice--their-automatic-and-controlled-components

Overall Assessment

The paper demonstrates moderate methodological rigor but is weakened by insufficient documentation of sample sizes, power analyses, and exclusion criteria, which hampers

confidence in the robustness of its findings. While the theoretical framework is articulated, the alignment between the proposed tripartite model and the empirical tasks is unclear, leading to ambiguous interpretations of automatic versus controlled processes. Evidentiary support for the central claims is mixed, with overgeneralizations about inhibition and automatic activation that are not fully substantiated by the presented data. Consequently, high-severity concerns about methodological transparency and theory-evidence alignment dominate the paper's scholarly standing.

1. Design-Theory Alignment

- **The free-response stereotype knowledge task in Study 1 may capture participants' personal beliefs or socially desirable responses rather than pure cultural stereotype knowledge.**

- Severity: **moderate**
- Justification: The theory distinguishes between cultural stereotype knowledge and personal belief endorsement. A free-response format can allow participants to edit or suppress stereotypic content, thereby mixing knowledge with controlled processes. This threatens the ability to test the hypothesis that high- and low-prejudice individuals possess equivalent stereotype knowledge.

Evidence:

- `methods/exp_1 -- field task_description`: Use of a free-response task instead of the typical adjective checklist to assess stereotype content
- `introduction -- field theoretical_framework`: Theory assumes equal knowledge of the cultural stereotype, distinct from personal endorsement

The thought-listing task in Study 3 may conflate controlled inhibition with strategic self-presentation, making it unclear whether observed non-stereotypic thoughts reflect genuine controlled inhibition of automatic activation.

- Severity: **moderate**
- Justification: The theory posits that low-prejudice participants inhibit automatic stereotypes via controlled processes. Yet, a thought-listing task can be influenced by participants' desire to appear non-prejudiced, especially when the goal of nonprejudiced identity is salient. This potential demand characteristic undermines confidence that the outcome measures the intended controlled inhibition mechanism.
- Evidence:
 - `methods/exp_3 -- field task_description`: Consciously directed thought-listing task assessing inhibition of automatically activated stereotype-congruent thoughts

- introduction -- field mechanistic_claims: Controlled inhibition requires cognitive capacity and intentional activation of nonprejudiced beliefs

2. Evidence-Theory Alignment

- **Study 2's claim that automatic stereotype activation is equally strong for high- and low-prejudice participants overstates what the ambiguous behavior evaluation task actually measures.**
- Severity: **moderate**
- Justification: The task assesses downstream evaluations rather than directly indexing the strength of automatic activation (e.g., via priming latency or physiological measures). Inferring equal activation strength from similar evaluation patterns conflates activation with response bias, which weakens the alignment between the reported results and the theoretical claim of equal automatic activation.

Evidence:

- results_and_discussion/exp_2 -- field key_findings: The experiment examined evaluations of ambiguous stereotype-relevant behaviors when conscious monitoring was precluded, and found stereotype-congruent evaluations for both groups.
- general_discussion -- field results_stated_to_support_theory: The authors state: "Study 2 suggested that automatic stereotype activation is equally strong and equally inescapable for high- and low-prejudice subjects."

The discussion generalizes that controlled processes can inhibit automatic prejudice for all participants, despite evidence that only low-prejudice subjects showed inhibition in Study 3.

- Severity: **moderate**
- Justification: The empirical result is limited to low-prejudice participants, yet the authors present the finding as evidence that controlled inhibition is a general mechanism applicable to all individuals. This overreach inflates the theoretical implication beyond what the data directly support.

Evidence:

- results_and_discussion/exp_3 -- field key_findings: Only low-prejudice subjects inhibited automatically activated stereotype-congruent thoughts and replaced them with equality-focused thoughts.

- `general_discussion -- field theoretical_conclusions`: The authors claim: "Study 3, however, provided evidence that controlled processes can inhibit the effects of automatic processing when the implications of such processing compete with goals to establish or maintain a nonprejudiced identity."

The paper extends the model's claim that automatic activation is independent of attitudes to a broad statement about "automatic stereotype-congruent or prejudice-like responses" without acknowledging that the studies only examined Black-related stimuli and White American participants.

- Severity: **minor**
- Justification: The conclusion extrapolates the observed independence to a general property of automatic prejudice, yet the evidence is limited to a single intergroup context. This limits the strength of the theoretical claim and should be qualified.
- Evidence:
 - `general_discussion -- field automatic_activation_independent_of_attitudes`: The authors write: "It would appear that the automatically activated stereotype-congruent or prejudice-like responses have become independent of one's current attitudes or beliefs."
 - `abstract -- field study_scope`: All three studies focus on stereotypes about Blacks and White participants.

4. Alternative Accounts

- **The tripartite model of attitudes is presented as an alternative theory but is not evaluated or discussed in the results or discussion sections**
- Severity: **moderate**
- Justification: The authors introduce the tripartite model as a competing explanation for the relationship between stereotypes and prejudice, yet they neither test predictions derived from it nor discuss how their findings bear on it. This omission leaves readers without a clear assessment of whether the data favor the focal model over this well-established alternative. Addressing it would strengthen the theoretical contribution.

Evidence:

- `introduction -- field alternative_theories`: The tripartite model of attitudes is listed alongside the inevitability of prejudice framework as an alternative account
- `general_discussion -- field alternative_accounts_addressed`: Only the Crosby et al. inevitability of prejudice account is addressed; the tripartite model receives no mention

The authors dismiss the inevitability of prejudice account without providing empirical evidence or a detailed theoretical rebuttal

- Severity: **minor**
- Justification: While the discussion mentions disagreement with the inevitability of prejudice framework, the critique is largely rhetorical and does not reference specific experimental results that contradict the claim. Providing empirical counter-evidence would make the dismissal more compelling.
- Evidence:
 - `general_discussion -- field alternative_accounts_addressed`: Crosby et al. inevitability of prejudice is argued against, but the authors only claim it "denies the possibility for change" without citing data that directly refute it

6. Methodological Concerns

- **The methods sections for the experiments are not provided, leaving sample size, power analysis, and exclusion criteria undocumented.**
- Severity: **moderate**
- Justification: Without clear reporting of sample size, power considerations, and participant exclusion rules, the reliability and generalizability of the findings cannot be adequately assessed. These omissions hinder the ability to evaluate whether the studies were sufficiently powered to detect the hypothesized effects.
- Evidence:
 - `methods/exp_1 -- field sample_size`: No sample size information is present in the extracted sections.
 - `methods/exp_1 -- field power_analysis`: No power analysis or justification for the chosen sample size is reported.
 - `methods/exp_1 -- field exclusion_criteria`: Exclusion criteria for participants are not described.
