CATEGORY NORMS FOR VERBAL ITEMS IN 56 CATEGORIES:

A REPLICATION AND EXTENSION OF THE CONNECTICUT CATEGORY NORMS¹

WILLIAM F. BATTIG²

AND

WILLIAM E. MONTAGUE

University of Colorado

University of Illinois

Complete normative data are presented for responses to 56 verbal categories by students from the Universities of Maryland ($N=270$) and Illinois ($N=172$). All 43 categories from the Connecticut norms are included, and complete data are presented for all responses given by each S to each category label within 30 sec. Additional data include (a) number of times each response was given first and mean rank of each response, (b) correlations between the various measures and between the Maryland and Illinois samples for each category, and (c) "category potency" measures and ratings for each category.

In 1957, Cohen, Bousfield, and Whitmarsh published as a mimeographed technical report a set of norms representing the

four responses given by each of 400 University of Connecticut students to each of 43 category names or descriptions. Attesting to the usefulness of these Connecticut category norms is the fact that the supply was completely exhausted within a few years due to the heavy demand resulting from the marked recent increase in research on organizational processes in free recall learning and memory. Thus the limited edition of the Cohen et al. norms has now become perhaps the most valuable single publication, and certainly the hardest to obtain, in the area of verbal behavior.

¹ Financial support for this project was provided by Research Grants HD-01062 and HD-03058-01 from the National Institute of Child Health and Human Development to the first author and by a research grant to the University of Illinois from the Air Force Office of Scientific Research. Because the collection and tabulation of the present data were performed entirely by hand and manually operated calculator, the efforts of those who accomplished this arduous task clearly merit far more than the usual acknowledgment. Two individuals in particular were responsible for the tabulation and calculations performed on the Maryland and combined data. Janis Hagstrom worked for almost 2 yr. in accomplishing the entire job of tabulating both frequencies and ranks for the Maryland sample. Diane Ray subsequently was responsible not only for combining these with the frequency tabulations from the Illinois sample, but also for the typing of these norms and the calculation of the correlational and potency indexes appearing in Table 1. In addition, Harold O. Kiess assisted with the collection of the Illinois data, whereas Genevieve Baker accomplished the tabulations for the Illinois sample. Finally, the tabulations of the potency ratings were jointly accomplished by Diane Ray along with Sally E. Battig.

² Requests for reprints should be sent to William F. Battig, Department of Psychology, University of Colorado, Boulder, Colorado 80302.

It was the inability of the first author to obtain a copy of the Cohen et al. norms that was directly responsible for the initiation of the present project at the University of Maryland in January 1965. His efforts to persuade Cohen of the desirability of reprinting the Connecticut norms were countered by Cohen's persuasive argument that after 8 yr. it would make more sense to redo them completely and bring them up to date. An end-of-semester excess of introductory psychology students over available experiments made it possible to obtain data immediately from nearly 200

Ss run in five large groups in a classroom setting. During the spring semester and summer of 1965, additional Ss were run individually or in smaller groups, bringing the Maryland sample to a total of 270 Ss. Data from an additional 172 undergraduates at the University of Illinois were obtained by the second author during the spring of 1965.

In addition to the 43 categories used by Cohen et al., 13 new categories were added, bringing the total to 56 categories. The added categories, identified as to numerical position in the norms as presented here, are the following:

- A Relative (No. 3)
- A Type of Reading Material (No. 6)
- A Kitchen Utensil (No. 11)
- A Part of Speech (No. 13)
- An Elective Office (No. 18)
- A Kind of Money (No. 35)
- A Type of Music (No. 36)
- A Nonalcoholic Beverage (No. 38)
- A Toy (No. 41)
- A Girl's First Name (No. 46)
- A City (No. 54)
- A State (No. 55)
- A College or University (No. 56)

METHOD

The present procedure, although basically similar to that used by Cohen et al. in most respects, incorporated several important changes. All Ss were provided with a small spiral notebook with at least 56 lined pages and were read the following instructions:

The purpose of this experiment is to find out what items or objects people commonly give as belonging to various categories or classes. The procedure will be as follows: First you will be given the name or description of a category. Then you will be given 30 sec. to write down in the notebook as many items included in that category as you can, in whatever order they happen to occur to you. For example, if you were given the category "seafood," you might respond with such items as lobster, shrimp, clam, oyster, herring, and so on. The words are to be written in the brown notebook, using a different page for each category. When you hear the word "Stop," you are to stop writing and turn over immediately to the next page of the notebook. You will then be given the name of another category, and again you are to write the names of as many members of that category as you can think of. This procedure will

be continued through a total of 56 categories, and you are to use a different page of the notebook for each category. Now please open your notebook to the first page and get ready for the first category.

For the initial large groups of Ss run at Maryland, both the instructions and category names were read by *E* from the front of the classroom, with timing accomplished by means of a stopclock. For these groups, five different unsystematic orders of presentation of the 56 categories were used, which provided that each category appeared in at least four different ordinal positions, with the mean position in sequence ranging between 21 and 36 for the various categories. One of these five orders, which had been used for the smallest of the five groups, was subsequently tape-recorded along with the instructions, with 30-sec. blank intervals between successive category names. This tape was used for the remaining Maryland Ss and for all of the Illinois Ss. Each category label was always repeated twice to insure that it was heard and understood correctly by all Ss.

The present procedure of allowing *S* to write down as many items for each category as he could in 30 sec. permitted an assessment of relative frequency of responses to the various categories. Because this measure of "category potency" was precluded by the Cohen et al. procedure of requiring their Ss to write down exactly four items for each category, it was later decided to obtain a further index of relative number of responses to the 56 categories. Ratings on a 7-point scale of the number of items *S* could think of belonging to each category were subsequently obtained from 207 introductory psychology students at the University of Maryland during a classroom lecture period. None of these Ss had participated in the original scaling procedure. For each category, these Ss were instructed to circle one of the numbers from 1 through 7, with the words "none," "average," and "very many" appearing below the numbers 1, 4, and 7, respectively. These Ss were further instructed to "work rapidly, and to give your initial impression as to the number of category members you could identify, rather than actually trying to count members of any individual category." The categories were presented in the form of four-page booklets, 14 categories to a page. To minimize sequential effects on the ratings, there were two different orders of the 14 categories for each of the four pages, and the four pages were unsystematically scrambled in order for different booklets.

RESULTS

All legible responses made by each *S* for each category were tallied separately for the Maryland and Illinois samples. For the Maryland sample, the rank of each response in each *S*'s response sequence for a given category was also recorded. The basic data, presented in the separate tables for each of the 56 categories which follow,

thus consist of the following four measures for each response given with a total frequency of 10 or more. In the first column for each response is the total frequency of occurrence of that response for the entire sample of 442 Ss. For each category, the responses are ordered from most to least, with the responses numbered as to rank order in this total frequency measure. Given in parentheses to the right of the total frequency measures are the numbers of times each response was given first in the response sequence (this number being omitted in all cases where the response was never given first). In the second and third columns are given the total frequencies (F) separately for the Illinois ($N=172$) and Maryland ($N=270$) samples. In the fourth and final column is given the mean rank position (R) of the response in the response sequence for each S in the Maryland sample who gave that response. This rank measure was not tabulated for the Illinois sample.

Responses with a total frequency of nine or less are listed alphabetically with no breakdown for the separate samples or rank measures presented, but with number of times a response was given first in the response sequence given in parentheses. For those preferring this information in the form of percentages, a conversion table is presented as an appendix to these norms, similar to that of Cohen et al. (1957).

In tabulating these norms, no attempt was made to separate different forms of the same response, so that many of the responses actually include more than one grammatical form or spelling of that response. Synonymous responses with substantially different spellings, however, are presented separately. All legible responses are included, even those which are obviously inappropriate to the category name. Thus only those responses where a misspelling was serious enough to make it unclear what English word was represented have been excluded from these tabulations. In an effort to maintain consistency in treatment of ambiguous cases, all the tabulations of the Maryland data were done by the same individual, including recording

of the ranks of occurrence. (It was this latter factor, incidentally, and a gross underestimate of the amount of time that this task would require that is largely responsible for the lengthy delay between the collection and presentation of the present data.)

Several additional comparative measures obtained for the 56 individual categories are summarized in Table 1. In an attempt to determine the geographical stability of the response frequencies for the Maryland and Illinois samples, Pearson product-moment correlation coefficients were computed between the two sets of frequencies for all responses given at least five times for one of the two samples. These correlations are presented in Column 1 of Table 1; the categories in Table 1 (as well as in the basic data tables which follow) are ordered in terms of magnitude of this correlation. Also computed for each category was the correlation for the Maryland sample between frequency (F) and rank (R) scores, including all responses given five or more times by this sample. These correlations are presented in Column 2 of Table 1. Column 3 contains the mean total number of responses for each category summed over both samples, whereas Column 4 contains the average rated frequency for each category. Also given in parentheses following each of the latter three indexes is the rank of the category for that index.

Some general comments about the results presented in Table 1 would appear to be in order here. First, the correlations between the frequencies for the Maryland and Illinois samples offer impressive evidence for the generality of these norms, except those few categories where members of the category are quite differently distributed in the East and Midwest (e.g., geographical subdivisions such as states, cities, and colleges or other geographically dependent objects such as trees, ships, fish, and snakes). These are the only instances, however, where this correlation falls below .9, and the median correlation for the 56 categories is .96. With the exception of states, all of these categories also show among the lowest frequency-rank cor-

TABLE 1

relations for the Maryland sample. Thus the considerable variations in the frequency-rank correlations appear at least partially attributable to differences in

reliability of the frequency measure. Those categories with the highest *F-R* correlations, however, seem to involve cases where the category includes a relatively small number

of predominant members and/or a consistent serial ordering of these members (e.g., unit of time, unit of distance, color, part of speech). Thus the rank information given in the present norms may be potentially quite useful, especially where it is important to specify the order in which the responses typically occur.

Table 1 also shows a substantial variation among categories both in the actual and rated response frequency measures. Further evidence for the existence of reliable category differences in response frequency or potency is provided by the substantial positive correlations of the ratings both with total actual frequency (.696) and

actual frequency for the Maryland sample alone (.665). These variations in category potency are clearly sufficient to be taken into account whenever categories or responses therefrom are selected for any particular investigation.³

* While in the process of tabulating these norms, the authors learned of a similar project undertaken at the University of Georgia by Karl P. Hunt and Milton H. Hodge which unfortunately involved sufficient procedural differences to preclude their combination or direct comparison with the present norms. These Georgia norms, however, include some 30 additional categories not used in the present study. Further information about them can be obtained by contacting Milton H. Hodge, Department of Psychology, University of Georgia, Athens, Georgia 30601.
